FWD allows server A to connect to remote FWD server B, to access the database instance managed by server B. This requires directory configuration for the remote FWD server access, and also a direct JDBC connection for the database.

Server A AFAIK at this time uses only remote dirty share, persistence and primary key calculations. Other caches (like FFCache, ORM Session cache) for the database served by server B, I think live on server A, while they can never be invalidated by server B.

This task is meant to investigate and find solutions for these cases.
